

Fiber Optic Communication Rate and Dispersion

Overview

Dispersion in a single mode fiber is the bottleneck of long haul optical communication systems, which limits the bit rate and repeater-less distance. Dispersion causes each pulse to broaden as it travels, because different components of the signal—different wavelengths, modes, or polarization states—propagate at slightly different velocities. This paper provides a. The Chromatic Dispersion of a fiber is expressed in $\text{ps}/(\text{nm}\cdot\text{km})$, representing the differential delay, or time spreading (in ps), for a source with a spectral width of 1 nm traveling on 1 km of the fiber. It depends on the fiber type, and it limits the bit rate or the transmission distance for a good. Fiber optic dispersion is crucial for understanding how light behaves in optical fibers. Light travels through optical fibers primarily via total internal. Light may follow a variety of paths through a fiber optic cable.
