

Working principle of circular fiber optic sensor

Overview

Fiber optic current sensors work by detecting changes in light as it interacts with a magnetic field created by an electrical current. These sensors rely on the Faraday Effect, which occurs when a magnetic field causes a rotation in the polarization of light passing through an. A fiber optic sensor measures a physical quantity by modulating the intensity, spectrum, phase, or polarization of light traveling through the optical fiber system. Radiation absorption creates electronic excited states that are trapped by localized defects for extended periods of time. Heating the material enables the trapped states to interact with phonons and decay into lower-energy. Understanding this core working principle (light modulation by external stimuli) is key to appreciating their revolutionary impact.
